Parking lot USB exercise

Contents	The USB drive contains personal information, such as family and pet photos, as well as work-related files, including a new hire letter and an employee shift schedule. These files may contain PII and sensitive employee information, so storing personal and work files together is not safe because losing or compromising the USB could expose both types of data.
Attacker mindset	An attacker could use Jorge's personal and work information to create convincing phishing or social engineering attacks against Jorge, other employees, or his relatives. The information could help an attacker impersonate an employee or target someone close to Jorge. If Jorge plugged the USB into a hospital computer, hidden malware could potentially provide unauthorized access to hospital systems.
Risk analysis	USB devices could contain malware such as ransomware, spyware, or a keylogger, which could infect a computer if an employee opened a malicious file. A threat actor could find PII, employee information, schedules, or other sensitive work documents and use them for identity theft, phishing, or social engineering. The hospital should restrict unauthorized USB devices, use antivirus and endpoint protection, encrypt sensitive data, and train employees never to plug in unknown USB drives.
